To the memory of my late sister Hauwa'u Tanimu, May her soul rest in eternal peace,
Ameen.

ACKNOWLEDGEMENTS

All praise is to Allah lord of the world, the most beneficent, most merciful. May His peace and blessing continue to be on our noble prophet, Muhammad bin Abdullah (S.A.W), his household, companions, and those that follow his guided path till the day of resurrection.

I would like to express my appreciation to King Fahd University of Petroleum and Minerals for giving me the opportunity to move to the next level of my ambition, through a full M.S. Scholarship.

My profound gratitude goes to my advisor, Dr. Khalid Alhooshani for his expertise, guidance, caring and most importantly his patience with me throughout the research period. To my committee members, Dr. Nisar Ullah and Dr. Oki Muraza, I said a big thank you for your support and advices. Special thanks goes to the Chairman, Chemistry Department for providing me enabling environment for study and research and other faculty members, staff and students of chemistry departments.

To my research group members, you mean a family to me and your support and advices at the moments of difficulties were well appreciated.

This piece would remain incomplete without expressing my thanks to my parents, they are always loving, caring and understanding. Your prayers of course keep me going and to Tanimu's family, I am proud of you all and thank you.

Thesis Title : Design of SOL-GEL Metal Oxide Thin Film Catalyst Support for Capillary Microreactor.

Major Field : Chemistry

Date of Degree: May, 2015

Ceria thin films as catalyst support for application in capillary microreactor was developed for the first time from freshly prepared cerium isopropoxide precursor using sol-gel approach. The thin film was characterized using powder XRD. FESEM image showed available pores within the dried film inside which palladium nanoparticles (Pd NPs) were immobilized. Film thickness was measured to be approximately 200 nm from the capillary SEM. Mean particle size and dispersion of Pd NPs was determined from the TEM images. FTIR and Raman spectroscopy were recorded and the results were comparable to DFT computational calculations and previously reported data. The Pd/CeO₂ immobilized capillary was tested for hydrogenation of phenylacetylene in a microreactor. Higher conversion and selectivity towards ethylbenzene were recorded at higher temperature, while selectivity towards styrene was favored at higher phenylacetylene concentration and hydrogen flow rate. Catalyst turn over frequency of 0.733 s⁻¹ was obtained for 158 ppm phenylacetylene hydrogenation at 60 °C and 0.5 ml.min⁻¹ hydrogen flow rate. Catalyst activity evaluation showed continuous decrease in catalyst activity for the first 4 days of operation and was then stabilized for further 2 days. ICP-MS result confirmed decrease in activity to be due to leaching of Pd in the Pd/CeO₂ capillary.

ABSTRACT (ARABIC)

ملخص الرسالة

الاسم الكامل: عبدالقادر تانيمو

عنوان الرسالة: تصميم اوكسيد معدن سول-جل غشاء رقيق داعم حفاز لمفاعل دقيق انبوبي شعري

التخصص : كيمياء

تاريخ الدرجة العلمية: مايو، 2015

للمرة الأولى تم تطوير غشاء السيريوم الرقيق كدعامة حفازه لتطبيقات في مفاعل دقيق شعري من مركب طليعي لللايزوبروبو اوكسيد السيريوم المحضر حديثا باستخدام نهج السول-جل. تم تشخيص الغشاء باستخدام مطيافية الاشعة السينية للبودة, ووافقت النتيجة ملف JCPDS لاوكسيد السيريوم. اظهرت صورت FESEM مساهات متوفرة داخل الغشاء الجاف, وتم ادخال جسيمات البليديوم النانوية داخلها. تم قياس سمك الغشاء ووجد حوالي 200 نانومتر من SEM للانبوب الشعري. تم تحديد حجم جسيمات البليديوم النانوية و تشتتها باستخدام صورة TEM. تم تسجيل طيف الاشعة تحت الحمراء ورمال وكان مقارنا مع حسابات DFT وبيانات تم دراستها سابقا. تم تجريب البليديوم/اوكسيد السيريوم في هدرجة فينيل استلين في مفاعل دقيق. تم تسجيل انتاجية و انتقائية عالية لايثيل البنزين في درجة حرارة عالية , بينما الانتقائية نحو الاستايرين كانت مفضلة عند تراكيز عالية من فينيل استلين وتيار هيدروجين عالي. تم الحصول على جهد اعلى للحفاز للدرجة 0.733 /1 ثانية لتركيز 158 جزء من المليون من فينيل استلين عند 60 درجة مئوية و 0.5 مل/دقيقة لمعدل سريان الهيدروجين. اظهرت فعالية الحفاز نقصان مستمر في فعاليته في اول اربعة ايام بعد ذلك استقرار في الفعالية بعد 2 اربين. نتائج ICP-MS اكدت نقصان الفعالية نتيجة الى رشح البليديوم خارج انبوب البليديوم / اوكسيد البليديوم الشعري.

CHAPTER 1

INTRODUCTION

Nanodevices, chips and capillary-based systems have grown significantly to become a very promising tools in the areas of chemistry, reaction engineering and biotechnology¹.

Compared to conventional batch reactors, capillary based-reactors have several advantages which include improved heat and mass transfer because of increased surface area to volume ratio¹⁻², precise temperature control enabling suppression of by-product³, efficient mixing⁴, higher conversion and selectivity⁵ and environmental friendly through a reduced usage of reagents and solvents⁶. A range of application of capillary reactors spans across diverse research areas such as catalysis⁷, nanoparticle synthesis⁸, sensors⁹, electrochemistry¹⁰ and polymerization¹¹.

Furthermore, capillary microreactors have been improved by using alternative energy transfer such as ultrasound¹² and microwave radiations¹³. Both radiations have been shown to be effective in increasing reaction rate, improving yields, shortening reaction time and recording high conversion^{12b, 14}. In a microwave oven, the heat can be transferred to the aqueous species efficiently and in ultrasonic bath, mass transfer and chemical reactions are intensified. Combined microwave-assisted or ultrasound-assisted syntheses with capillary microreactors have found many applications in synthetic chemistry¹⁵. Chemical sectors including petrochemicals, fine chemicals and pharmaceuticals have invested in nanodevices and capillary reactors in order to develop green and sustainable continuous manufacturing with less waste¹⁶. Herein, focus is given

to the different immobilization methods, various characterization methods of immobilized capillary and the performance of immobilized capillary in some reactions.

1.1 Principle of Microreactor

Microreactor technology within the past two decades has evolved to become the key technology for process intensification. ‘Lab-on-a-chip’ as it is proudly called, microreactors have contributed to the minimization of reagents and energy wastage due to their small dimensions which in most cases do not exceed 1mm. Also the small volume of microreactors enables safe and easy handling of hazardous and highly exothermic reactions while facilitating fast and easy parameter screening. Efficient heat and mass transfer in microreactors also significantly increases the productivity when compared to classical batch reactors.

The ability to increase effectively the productivity through running a series of continuous reactors concomitantly is another interesting feature of microreactor technology. Some reactions studied successfully using microreactor technology include Suzuki-Miyaura coupling reactions, Wittig reactions, hydroformylation reactions, hydrogenation reactions, Diels-Alder reaction etcetera.

1.2 Characteristics of Microreactor

Apart from size, there are some other properties of microreactor that made it better in performance and handling to conventional batch reactors. Some of these properties are efficient mixing ability coupled with generation of extended phase interface, safety in

handling toxic and explosive reactions, effective and easy temperature, pressure, time and flow velocity adjustment while maintaining efficient heat transfer.

1.2.1 Efficient Mixing Ability

Mixing regime constitute the integral part of microreactor and the laminar flow regime of the fluids made microreactors different from classical continuous flow reactors. This regime is define by the Reynolds number Re , a dimensionless number which is a function of velocity u , travelled length L , density ρ , and viscosity η of the fluid.

$$Re = u\rho L/\eta$$

The Reynolds number ranges from 10 – 500 for laminar flow regime in microreactors which is due to fast lateral diffusion, resulting in intensive mass transfer which occurred between layers and the consequence is residence time convergence¹⁷. Lamina flow has the advantages of restraining gradient formation in concentration, temperature, pressure, volume and time. Generally the channel diameter of microreactors lie between the range of 1mm - 100 μ m for chemicals production resulting in diffusion timescale of <1s for gases and even less for smaller channel diameters. However the diffusion timescale for liquids is in the range of seconds to minutes thus giving possibility of lateral diffusion as limiting factor for fast reactions. In order to reduce the diffusive barrier, preliminary lamellar micromixing is connected for intensification of mass transfer. The result is decrease in the time of response and increased space-time yield. Effective mixing with controlled molar ratio of reactants give rise to high yield and selectivity, hence suppressing side reactions.

Figure 1.1 Efficient mixing in a microreactor: The green color indicates the perfect 1:1 mixture of reactants from inlet A and inlet B.

1.2.2 Heat Exchange/Temperature Control

The study of reaction kinetics and product characterization is known to be well influenced by temperature of the system and therefore controlling the temperature is paramount to achieving the desired selectivity in any chemical process while minimizing the reaction time. Heat exchange in microreactor is so efficient that it warrant immediate correction of temperature changes, unlike in large-scale reactors where temperature changes require some time to make effect on the system. This affords suppression of undesired by-product in microreactor. Since lamina flow regime is obtained with microfluidic devices, molecular diffusion theory could be used to determine the approximate time taken for thermal mixing across a microchannel and the heat transfer to lamina flow of fluids is described using the Nusselt number Nu which relates to the convective heat transfer coefficient α , characteristic length L , and thermal conductivity of fluid λ by the equation:¹⁸

$$Nu = \alpha L / \lambda \quad (\text{dimensionless})$$

The Nusselt number could also be described as temperature gradient on a surface.

1.2.3 Surface Area to Volume Ratio

The small inner volume of a microreactor coupled with strong heat exchange ability result in high surface area-to-volume ratio, which enables rapid dissipation of heat generated during exothermic reactions. The heat transfer in terms of thermal diffusivity coefficient a , is related to the heat timescale t_w and the travelled length of the fluid L by the equation:

$$t_w = L^2/a$$

More recently, the advent of heat exchanger in microreactors now allows fast heat exchange to and from the reactor making it possible to study even explosives reactions under isothermal conditions.

1.2.4 Pressure Control

For gaseous reactant(s) flowing through capillary microreactor, very high pressure could be attained due to the microsize of the reactor. But interestingly, reactions have been

carried out safely under high pressures and up to above 400 °C in microreactors which is not the case in conventional batch reactors. Hence microreactors stand out to be the ideal reactors for studying reactions under supercritical conditions¹⁹.

In summary, microreactors technology offers the following advantages:

1. Scale-independent synthesis
2. High yield and selectivity
3. Accelerated process development
4. Enhanced safety
5. Product profile improvement

Catalysts immobilization for heterogeneous catalysis in microreactors have been successfully studied with the catalysts forming thin films coatings or as monolith.

a) Thin films open tubular

Thin film is a layer of nanometer fractions to several micrometers in thickness, prepared from concentrated solutions. It is two dimensional and can be formed in the inside or outside of capillary microreactor by coating. Coating is done at room temperature while calcination and densification are performed at elevated temperature. Drying in air is usually fast and crack free due to the thin diameter of the films, thus forming adherent and continuous complete surface coverage. In the course of drying, thin films undergo shrinkage of the type anisotropic shrinkage.

b) Monolith formation

Formed from dilute solution of its precursors, a monolith is microporous preform that is nearly net shaped. Two types of solutions can be used to form monolith; alkoxides gel (with pore size < 10nm) and colloidal gel (with pore size > 10nm). Because of the three dimensional geometry and isotropic shrinkage pattern, crack free drying of monolith pose a big challenge. Both thin films and monolith coating can be performed on multi-channelled microreactor containing many silica capillaries held together using adhesives.

1.3 Silica Capillary

Silica could be considered as an interlinking SiO_4 polymer from silicic acid with the structure terminating at the surface either in a siloxane group ($\equiv\text{Si}-\text{O}-\text{Si}\equiv$, oxygen on the surface) or silanol group ($\equiv\text{Si}-\text{OH}$)²⁰. This nature of silica surface enables silica capillary to partake in chemical reactions with various organic and inorganic compounds, warranting immobilization of different functionalization in either the outer or inner surface of the capillary according to the individual desire. Most prominent of these reactions are with chlorosilanes,²¹ silanes²² and siloxanes²³. The silica capillary upon immobilization with a functionalized group directly or via a support can have many applications in chromatography,²⁴ catalysis²⁵ and biomaterials/biotechnology²⁶. Fused silica capillaries with external protective polyimide coating and of various diameters are available commercially.

Silica

Scheme 1

1.4 Sol-Gel Process

A process where solution or sol undergoes a sol-gel transition, thus becoming rigid and porous mass²⁷. Recently the technique is conveniently applied in immobilization of various organic, inorganic and biomolecule frameworks²⁸. Prominently used example of sol-gel process is system of tetraethoxysilane (TEOS) and water mixed in a mutual solvent like ethanol²⁹. Two steps are involved: formation of sol (dispersions of colloidal particles in liquid), then gelation of the sol to wet gel, which later dries.

1.4.1 Formation of Sol

When TEOS is mixed with appropriate amount of water in a mutual solvent (since TEOS is immiscible with water), the hydrolysis process initiates along with condensation. The product of complete hydrolysis is silicic acid ($\text{Si}(\text{OH})_4$), but the hydrolysis does not get to completion before condensation starts, usually between two silanols or a silanol and

ethoxy group to form a siloxane group, resulting in elimination of water or ethanol. Both processes can be promoted under acidic or basic S_N2 conditions.

Hydrolysis

Condensation

Scheme 2

1.4.1.1 Acid Catalyzed Hydrolysis

Hydrochloric acid is mostly used for catalysis of the hydrolysis process, although acetic acid, nitric acid and sulfuric acid have also been reported. The proposed mechanism is preceded by rapid protonation of –OR or –OH substituent bonded to Si, causing shifting of electron cloud away from Si, hence susceptible to attack by water molecule to form the transition state and subsequently ethanol or water will be eliminated.

1.4.1.2 Base Catalyzed Hydrolysis

Ammonia solution is generally used in base catalyzed sol-gel hydrolysis process. It hydroxyl ion being highly nucleophilic initiate the reaction by attacking Si which has the largest positive charge in TEOS.

a) acid-catalyzed - pH < 2

b) base-catalyzed - pH > 2

Scheme 3

1.4.2 Polycondensation

In acidic medium, due to slow hydrolysis, linear molecules that are occasionally cross-linked are formed as condensation continues and these chains entangle and form branches which result in gelation. However, in basic medium, where hydrolysis is fast highly branched clusters are formed that gelled by linking of the clusters. Studies conducted to compare the properties of gel formed from acid and base catalyzed hydrolysis showed TEM of acid catalyzed to exhibit a very fine microstructure and with very small pores that appear quite uniform throughout the material while TEM images of base catalysed showed resolved silica particles of larger pore size³⁰. The surface of acid catalysed also showed more available silanols as further confirmed by the TGA results.

1.4.3 Gelation

When sufficient interconnected siloxane bonds are formed, colloidal particles or sol resulted which linked together with silica species after some time to form 3D network. As

gelation is being approached, sharp increase in viscosity occurred and instantly the sol lost its fluidity, forming an alcogel. Based on the method of solvent removal from the alcogel during drying, three kinds of gels are identified; xerogel, anbigels and aerogel.

1.4.4 Aging

Polycondensation reaction is allowed to continue in order to have more bonds formation and thus additional crosslinking. This makes the structure and properties such as strength of the gel to change as it aged.

1.4.5 Drying

At the last stage of gelation, solvent and water evaporate from the interconnected pore network resulting in gradual volume shrinkage of the solid alcogel. In order to prevent cracking while drying of the wet gel, controlled and monitored conditions must be put in place especially in large monoliths. When drying is achieved using thermal evaporation, xerogel of moderately low surface area and porosity results. Drying under supercritical conditions forms aerogel with large pores structure while drying at ambient temperature after changing the pore fluid with nonpolar and low surface tension organic solvent results in ambigel with 80-90% porosity of aerogel.

Figure 1.3 The sol gel process

Figure 1.4 Applications of Sol Gel process

1.5 Statement of Research Problem

Most of the heterogeneous catalyses previously studied were based on γ – alumina, silica and titania supports. γ – alumina is used as catalyst support because of its surface area, pore size, pore volume and amphoteric character, although it suffers lack of chemical and hydrothermal stability³¹. This was later addressed by using mixed oxide films. Silica and titania thin films are frequently used due to their easy access, chemical and thermal stability, porosity and readiness to bond with different types of organic groups. Successes recorded in the use of these films has limited further research into novel metal oxide thin films which could offer better properties.

1.6. Objectives of Research

1. To develop new (cerium oxide) catalyst support in capillary microreactor.
2. Characterize the developed thin film.
3. Immobilize metal catalysts nanoparticles in the thin films.
4. Test run the developed capillary in some catalytic conversions.

1.6 Significance of the Study

The study targets development of novel thin film support for capillary microreactors which could be used as catalysts support for many catalytic conversions, one of the important research area defined in the “Strategic Priorities for Nanotechnology Program” of the Kingdom of Saudi Arabia.

CHAPTER 2

LITERATURE REVIEW

2.1 Catalyst Support

Since catalyst activity depends on the surface atoms, then anything that can maximize the surface area of the catalyst and enhanced the catalyst adhesion to the substrate is considered a catalyst support. The support may also affect the dispersion and shape of the catalysts particles³². Typical catalysts support are silica³³, alumina³⁴ and titania^{7a}.

2.1.1 Silica Support

Most of the heterogeneous catalysis studied are based on silica support due to its easy access, chemical and thermal stability, porosity and readiness to bond with different types of organic groups. For example in order to introduce –COOH functionality on a thin film, Brinker and co-workers fabricated –CN terminated silica thin films by an evaporation induced self-assembly (EISA) method using Brij56 nonionic surfactant which acted as a directing agent³⁵. Nakamara et al. reported the surface modification of capillary by injecting silica suspension into a capillary of 60 cm length via Teflon tube connected to syringe while ensuring absence of bubbles and placed it horizontally in an oven at 60-120 °C³⁶. After several hours of drying, the Teflon tube was removed from the capillary and further allowed to dry for 12 h at 90 °C. The modification can be furthered by flushing of octadecyltrimethoxysilane solution in toluene into the dried capillary, followed by heating at 100 °C for 30 min in order to activate the inner surface. By heating a mixture of Pd(PPh₃)₄, tetra(ethylene glycol), and Si(OMe)₄ and the resulting black suspension

treated with water, a silica gel containing trapped Pd nanoparticle was prepared and after washing and drying of the gel, it was used for the catalysis of Heck reaction³⁷. Sonogashira cross-coupling has also been studied using silica-supported palladium complexes³⁸. Stille coupling reactions were also reported to be catalysed using Pd catalyst supported on amorphous silica (SiO₂/TEG/Pd) prepared from Pd(PPh₃)₄ in tetra(ethylene glycol) and Si(OMe)₄ via the sol-gel method³⁷. Other reactions studied using silica-supported catalysts are Suzuki-Miyaura coupling³⁹, carbonylation of aryl halides⁴⁰, cyanation of aryl halides⁴¹, allylic alkylation⁴² and Buchwald–Hartwig reactions⁴³.

2.1.2 Alumina Support

γ – alumina among other known alumina is more often used as catalyst or catalyst support and this is not unconnected to its surface area, pore size, pore volume and amphoteric character. Although the oxide has this favourable combinations, there is still something critical for its catalytic application that is practically lacking which is chemical and hydrothermal stability³¹. This has limited its application in catalytic support, however some researchers have tried to improve the properties when using it as support. For example Bravo et al.^{5b}, Lim et al.⁴⁴ and Park et al.⁴⁵ reported independently the use of alumina/zirconia support prior to coating with the catalyst. CeO₂ and La₂O₃ promoted α -alumina support was used for hydrogen production in microreactor and CeO₂ additive was observed to contribute more to the surface area increase than La₂O₃⁴⁶. Kawamura and co-worker formed a thin Al₂O₃ boehmite layer on a microchannel using Al₂O₃-sol prepared by hydrolysis of aluminium isopropoxide⁴⁷ while Hwang et al. pre-coated the inner surface of microreactor with alumina⁴⁸. In another research conducted by Zapf et

al.⁴⁹, alumina binder formed from γ -alumina, water, PVA and acetic acid was used as the catalyst support, although Haas-Santo reported that the calcined surface layer formed from this method used to be non-uniform⁵⁰. Kundu et al. compared the stability and performance of alumina, zirconia and 1:1 mixture of both, as catalyst support for the study of steam reforming of methanol⁵¹.

2.1.3 Titania Support

By atomic layer deposition, TiO_2 catalyst support formed from titanium tetrachloride and water was deposited on a borosilicate glass substrate for microstructured reactors⁵². Li Xiaohong used TiO_2 coated on SBA-15 as catalyst support for liquid-phase hydrogenation of benzaldehyde and found it effective⁵³, while Bian et al. studied the effect of experimental conditions on mesoporous TiO_2 thin films for platinum catalyst support by varying substrate type, aging conditions and films post-treatment method⁵⁴. In other selective hydrogenation reactions in a capillary micro reactor, colloidal solution of metal or polymetallic nanoparticles was first mixed with titania precursor, surfactant and solvent then coated in the capillary after ageing⁵⁵. However, the coating of mesoporous titania thin films without metal incorporation was also reported^{7a}, in which case the films acted as both catalyst and catalyst support.

Some researchers used porous polymer monolith synthesized *in situ* as support for catalysts⁵⁶. GMA-co-EDMA was used as monolith support for the anchoring of palladium complex catalyst in a study conducted by Bolton et al.⁵⁷. The monolith was synthesized *in situ* following a method reported by Preinerstorfer et al.⁵⁸ after treatment of the inner surface of capillary. Poly(chloromethylstyrene-co-divinyl benzene) was also

used as a polymeric monolith pre-catalyst support and was synthesized in situ using a mixture of 60% porogens, 24% monovinyl monomer and 16% crosslinking monomer⁵⁶, a 6:4 porogen/monomer ratio⁵⁹.

Several metal oxide supports have been reported for gold nanoparticles catalyst in selective hydrogenation of unsaturated aldehydes and ketones. Okumura et al. for example used Al_2O_3 , SiO_2 and TiO_2 in their research⁶⁰, Mohr et al. used titania and zirconia⁶¹ while Milone et al. used goethite, maghemite, hematite and iron oxyhydroxide⁶². SiO_2 -supported Au/TiO_2 and Pt-Sn/TiO_2 were also used to study the kinetics of liquid-phase hydrogenation of citral^{55b} and SiO_2 was as well used for niobium and titanium catalysts support prepared via solventless organometallic precursor dry impregnation (OM-DI) and liquid-phase grafting post synthesis methods⁶³. Ceria was reported to have large application in electric and electronics due to high electric and ionic conductivity and catalytic applications⁶⁴, however little was reported about its application as thin films and no report for thin film capillary application. Therefore in this research, ceria thin film was developed from cerium isopropoxide via the sol gel process and coated in capillary.

2.2 Catalyst Immobilization

In general, both heterogeneous and homogeneous catalysts can be applied in capillary microreactor. In heterogeneous system, the major challenges are the packing and retention of the supported catalyst inside the microreactor coupled with the high back pressure over the capillary tubes⁶⁵. Contrastingly, in homogeneous system, the main challenge is the need for steady and constant plug flow behavior⁶⁶. In developing a

capillary microreactor for heterogeneous catalytic reactions, the main task is how to deposit the catalyst in the capillary microreactor so as to have very stable and uniform immobilized surface.

Several studies reported different ways of achieving excellent catalyst deposition in microreactor beginning with preparation of the capillary wall in order to gain better catalyst adhesion, a process known as pretreatment, to calcination of the post coated capillary.

2.2.1 Pre-treatment

Surface pre-treatment has to do with preparing of a pre-coated surface towards increased surface adherence in order to achieve full potential for immobilization of catalyst. Free electrons, ions, radicals, metastables and UV radiation can hit substrate surface with high energies resulting in breakage of molecular bonds on the surface. Free reactive radicals are generated from the surface which can react rapidly with the incorporating groups to form cross-link and other functionalities. Several methods have been used that result in excellent pre-treatment some of which include:

2.2.1.1 Plasma Oxidative Treatment

Involves combustion of hydrocarbon fuel to generate flame plasma which is used to modify the substrate surface without affecting its bulk properties. This method had been used for silica⁶⁷ and stainless steel substrate⁶⁸ pre-treatment. Plasma oxidation is most effective within 5-10nm of the substrate surface and it offers great deal of wettability and aging stability to the surface. Three factors can affect nature of the oxidation: the flame chemistry, substrate distance from plasma and dwell time.

2.2.1.2 Anodic Oxidation

An electrochemical method of producing oxide film on the surface of a substrate by oxidation of the anode electrode dipped into acid solution. The method find application in surfaces and properties modification of titanium and aluminium⁶⁹ due to corrosion resistance and biocompatible resultant mechanical properties. In Pt electrodeposition on boron-doped diamond, anodic oxidation pre-treatment plays dual role: at short-term anodic pre-treatment, Pt deposition was increased and at longer pre-treatment time, the deposition was inhibited which was explained based on the wettability and stability of the surface.

2.2.1.3 Thermal Oxidation

Through high temperature heating in the range of 800 – 1200 °C inside furnace, oxide can be formed on the surface of substrate due to fast oxidation with environment water vapour or oxygen. This techniques has been reported in the pre-treatment of silica⁷⁰ and gold surface was also thermally activated to such a level that it undergoes oxidation at a lower potential than a copper surface⁷¹.

2.2.1.4 UV Radiation

High energy UV radiation can cause the excitation of valence electron or even break chemical bonds. When this occurs on substrate, atoms, ions and radicals formed can react with atmospheric oxygen or other functionalities. This treatment was used by Bolton and co-workers⁵⁷ in an attempt to develop a palladium complex anchored solid macroporous monolith for catalysis in capillary microreactor following a procedure described by Rohr⁷² and Greenway⁷³. In the method, inner surface of capillary is activated by the

excitation of photoactive species such as benzophenone using UV light resulting in hydrogen abstraction and formation of free radical on the polymer substrate which accord quick and effective binding with many other functionalities⁷⁴. In the studies of selectivity control in hydrogenation reactions⁷⁵, UV irradiation on TiO₂ layer deposited by atomic layer deposition⁷⁶ was done to render it super hydrophilic⁷⁷ after which the metal or polymetallic nanoparticles got impregnated on the layer.

2.2.1.5 Chemical Oxidation

Surface oxidation through chemical reaction as pre-treatment method is highly pronounced and most adopted by researchers. Studies conducted on prevention of inertial effects during the process of coating by the use of multi-channeled structures involved cleaning of the microchannel with piranha etch, then water, then ethanol and dried it in an oven at 80 °C before coating with the catalyst⁷⁸. While comparing the enzyme reactivity of SiO₂ supported capillary with non SiO₂ supported capillary, the latter was treated with piranha solution for 12 h at 25 °C and then rinsed with pure water³⁶. Pre-treatment with sulphuric acid solution or seeding with silicalite seeds was used in the coating of zeolite films on the channels of stainless steel reactor⁷⁹. Three step treatment was employed in the optimization of coating parameters of microchannel reactor using 99+% acetone, 99+% acetic acid, 1.0M ammonium hydroxide, 85 wt.% phosphoric acid and 29-32% hydrogen peroxide⁸⁰. In methanol steam reforming using microchannel reactor, the pre-treatment was done by dipping a micro-channeled stainless steel into concentrated nitric acid for 45 min followed by washing with demineralized water⁵¹. Anisotropic wet etching with 30 wt.% KOH solution was applied on micro-channels as pre-treatment strategy in the investigations of preassembled methods of microreactors

coating⁴⁸. Pre-treatment of inner surface of capillaries in the investigation of the applicability of poly(chloromethylstyrene-*co*-divinyl benzene) catalyst supported-polymer as monolith in capillary microreactor for Suzuki-Miyaura and Sonogashira reactions⁵⁶ was done by rinsing the capillaries with acetone followed by 0.2 M NaOH at rate of 2.0 $\mu\text{l}.\text{min}^{-1}$ for 2 h. After rinsing with water and 0.2 M HCl under the same condition, the capillaries were further rinsed with water, followed by ethanol at 2.0 $\mu\text{l}.\text{min}^{-1}$ for 30 min and lastly 20 wt.% solution of 3-(trimethoxysilyl)propyl methacrylate in ethanol at pH 5 was flushed through the capillaries at 0.25 $\mu\text{l}.\text{min}^{-1}$ for 1 h, as surface modifying agent, then washed with acetone and dried with air for 24 h⁵⁸. Adhesion properties of the inner surface capillary was enhanced in a research conducted by Rebrov and co-workers^{7a, 55a} by treating the capillary with continuous flow of 1 M NaOH at rate of 0.03 $\text{ml}.\text{min}^{-1}$ for 15 min, followed by flushing with demineralized water, after which the capillary was dried and calcined in an oven at 300 °C and 16 mbar. Protasova et al., apply similar pre-treatment procedure by passing 1 M NaOH solution through the capillary at 70 °C for 2 h, then washed the capillary with water and ethanol at 25 °C^{55b} while Zeng et al., used 1 M NaOH solution for 1 h, then washed with deionized water followed by 0.1 M HCl solution and deionized water again⁸¹. The inner surface of a glass capillary, in study done by Ng et al., was filled with 2-aminopropyl trimethoxysilane solution in methanol and left for 15 h at 25 °C after washing of the capillary with 1 M NaOH, water and ethanol in order to enhance covalent bonding with the catalyst⁸². Similar procedure was also used by Kobayashi research team in developing a microfluidic device for conducting multiphase hydrogenation reactions^{7b}.

2.2.2 Sol Solution

Excellent design of a sol solution is pre-requisite to successful catalyst deposition in a capillary microreactor. Basic properties that need to be monitored in sol solution preparation are viscosity, surface tension and time-to-gel with the last property being particularly more important because film formation, drying and creation of pore must be rapid. Some or all of the following are what constitute the sol solution: catalyst precursor, support precursor, surfactant, deactivating agent, acidic/basic/fluoride catalyst and solvent(s). Different methodologies were reported in preparation of a sol solution for the coating process based on the research needs. For synthesis of –COOH terminated highly ordered mesoporous thin films, cyanoethyltriethoxysilane used as cyanide precursor was mixed with TEOS, Brij56, hydrochloric acid, ethanol and water, which upon deposition resulted in the cyano-functionalized mesoporous film and on hydrolysis with sulphuric acid yield the corresponding –COOH derivatized mesoporous thin films³⁵. The sol solution of silica coated microcapillary was prepared by addition of silica nanosphere to a mixture of water and ethanol, then injected into the pretreated capillary with a syringe pump³⁶. Another study utilised only Pd acetate as catalyst precursor and dimethylformamide as solvent in preparation of sol solution which was filled into borosilicate capillaries¹³. In preparing the sol solution of CuO/ZnO/Al₂O₃ catalyst, the mixed oxides were crushed and sieved to <24 µm diameter, then added to a mixed solution of boehmite, deionized water and nitric acid, and ball milled overnight⁷⁸. Studies on kinetics of methanol synthesis over CuO/ZnO/Al₂O₃/V₂O₃ catalyst used 10 wt.% suspension of the ball milled and sieved form of the catalyst in 2-propanol for coating after sonication⁸³. Phan et al. used 1 wt.% of polyvinyl alcohol instead of 2-propanol in

preparing sol solution for ball milled CuO/ZnO/Al₂O₃ precursor⁸⁴. Aluminium secondary butoxide and zirconium (IV) propoxide were used as precursors for preparing sol solutions of alumina, zirconia and 1:1 mixture of both using the method described by Zeng⁸⁵. Hydrolysis of alkoxide was protected during the sol preparation by addition of acetylacetone in 1:1 ratio with alkoxide⁵¹. Hwang and co-worker used two different solvents to prepare Cu-Zn-Al₂O₃ catalyst slurry after ball milling; alumina sol and deionized water which were coated on alumina pre-coated microchannel⁴⁸. While attempting two different ways of anchoring metal/bimetallic nanoparticles on films and capillaries, Muraza et al. used two different approaches; first, thin films were prepared separately and then nanoparticles were anchored on the films and secondly, one-spot synthesis was done containing the films as well as the nanoparticles^{75, 86}. Appropriate amounts of pluronic F127, titanium tetrabutoxide (TTB), ethanol, H₂O and nitric acid were used in preparing sol solution for mesoporous titania thin film coating^{7a}. Titanium tetrabutoxide (TTB) was substituted by Ti(O-2Pr)₄, and then Au nanoparticles were added in preparation of sol solution for Au/TiO₂ deposition in a one-spot synthesis procedure^{55b}. Many thin films parameters could be successfully varied through altering of sol solution components or changing their percentage. Tetraethoxysilane (TOES) was reported to be an excellent sol-gel precursor due to its structure which enables fast drying thus preventing cracking⁸⁷. Lu et al. in their research varied the metallic ratio in a nanoparticle by changing initial concentration of the metal precursor⁸⁸ while by changing the amount of protecting agent, Alberius successfully changed the nanoparticle size⁸⁹. The porosity of films was also reported to be changed by increasing the percentage volume of surfactant or changing the surfactant⁹⁰.

2.2.3 Coating and Post Coating

In order to flow the sol solution through capillaries for coating, two methods are commonly employed. They are injection method and gas-fluid displacement method. Both used pressure to overcome the sol solution viscous drag⁹¹. In injecting catalyst suspension into a capillary, Nakamura et al. connected a Teflon tube to the microcapillary and used a syringe to inject silica suspension into the microcapillary³⁶. Chen and co-worker adopted similar approach in filling Pt/Al₂O₃ catalyst sol solution into closed microchannels⁹². Hayes and Malik used capillary filling/purging device in the gas-fluid displacement method, by inserting one capillary end into the pressurization chamber until it moves into a solution vial positioned inside the chamber, then airtight the capillary filling system before discharging inert gas⁹³. Bravo et al. also used the gas-fluid displacement method in coating CuO/ZnO/Al₂O₃ catalyst in inner surface of capillary^{5b}. The sol solution could be kept for some time in the capillary before is finally expelled (flow coating) or allowed to slowly dry and then calcined (fill-and-dry)^{48, 94}. In the case of monolith formation, the sol solution is left undisturbed in capillary until gelation is complete, then pressure is slowly released through the capillary⁹⁵.

After coating, a post coating treatment is applied by subjecting the capillary to thermal conditioning in the form of slow temperature programming with continuous flow of inert gas in order to complete bond formation between the silica capillary and the immobilized system and at the same time increase the strength of the bonding hence decrease leaching possibility of the catalyst. For example after drying for 12 h at 90 °C, octadecyltrimethoxysilane in toluene was further flushed through an already treated capillary and heated at 100 °C in an oven for 30 min³⁶. Kunde et al. conditioned their

microchannel, after coating it and allowing it to dry at room temperature, by first heating at 80 °C in an oven for 5 h and then calcined at 500 °C for 2 h in order to decompose the carbon species present in the sol solution, thus increasing the surface area⁵¹. Rebrov subjected the capillary to 300 °C heating at 15 mbar in an oven after drying it^{7a} and Protasova used the same 300 °C heating but under a 10 mbar pressure in the post treatment^{55b}.

Figure 2.1 a) Injection method with syringe b) Capillary filling/purging device

2.3 Characterization of Immobilized Capillary

Many techniques have been used for studies of properties such as surface morphology and chemical composition of coated surfaces. Most of the techniques were chosen based on research demand, instrument availability and expertise in operation, and ability to interpret result. For inner surfaces of capillaries, characterization can be done by

removing catalyst film on the inner surface and use it for the analysis. However, this is only possible if the capillary diameter is large enough as in the case of 1150 μm capillary used by Shore et al in their research¹³. When the capillary diameter is quite small, a similar coating is done on a flat surface and used for the characterization^{7a, 55b}.

2.3.1 Inductive Coupled Plasma

Metal loading in coated capillary is determined by using inductive coupled plasma (ICP). For example Gomann et al determined palladium content in the polymer-supported capillary microreactor using ICP-MS⁵⁶, while Ng et al quantified Pd loading in Palladium coated capillary using ICP-AES⁸².

2.3.2 Thermogravimetric Analysis

Variation in physical or chemical properties of coated surfaces as a function of increasing temperature can be determined using thermogravimetric analysis (TGA). For example TGA of $-\text{COOH}$ derivatized mesoporous thin films in argon to temperature of 800 $^{\circ}\text{C}$ showed *ca.* 14% weight loss between 200-450 $^{\circ}\text{C}$ which was thought to be result of decomposition of $-\text{CH}_2\text{CH}_2\text{COOH}$ groups³⁵. Porous system of styrene divinylbenzene resin used as platinum catalyst support was found resistant to heating up to 160 $^{\circ}\text{C}$ with 4.4% surface area lost in its TGA result⁹⁶.

2.3.3 Adsorption-Desorption Isotherm

Adsorption-desorption isotherm provide information on the size and shape of pores based on the type of hysteresis loop formed⁹⁷. A type IV isotherm typical of mesoporous materials was reported in the N_2 adsorption-desorption isotherm performed by Liu et al³⁵

and Rebrov et al^{7a} also reported similar result. Ethanol adsorption-desorption isotherm recorded with ellipsometric porosimetry (EP) was also reported^{52, 55b}.

2.3.4 Electron Microscopy

Crystal structural information, direct surface imaging, elemental distribution and composition are routinely determined using electron microscopy such as transmission electron microscopy (TEM), high resolution electron microscopy (HREM) and scanning electron microscopy (SEM). In order to confirm complete filling of capillary with monolith, Bolton and co-worker used SEM and observed the resulting images⁵⁷. Sample imaging was also carried out for Pd coated capillary and the SEM results showed highly porous and nanometer sized crystallites¹³. Field emission scanning electron microscopy (FESEM) was used to determine the cross-sectional morphologies and thicknesses of catalysts layers coated onto micro-channels⁴⁸. Rebrov et al. used transmission electron microscopy (TEM) and field emission gun scanning electron microscopy (FEG-SEM) to determine the morphology and cross sectional thickness of coated fused silica capillary respectively^{7a}.

2.3.5 X-ray and Neutron Diffraction

Complete structure description could be achieved using X-ray diffraction (XRD) and neutron diffraction. XRD was used to determine the phase composition of Pt-Ru surface coated microstructured reactor⁵² and the crystalline state of mesoporous titania thin films⁵⁴.

2.3.6 NMR

Information concerning the nuclei environment is obtained using NMR such as ^1H NMR, ^{13}C NMR, and ^{29}Si MAS NMR. ^{13}C , ^{29}Si and ^{31}P cross polarization magic angle spinning (CP/MAS) NMR were used in characterization of surface rhodium siloxide complexes⁹⁸.

2.3.7 EPR and Mossbauer Spectroscopy

Electron spin resonance (ESR) or electron paramagnetic resonance (EPR) could give access to number and location of unpaired electrons while oxidation state of some metals and coordination number in complexes can be determined using Mossbauer spectroscopy. Wang for example studied the chemical state of Manganese in Mn/SiO_2 , $\text{Rh-Mn}/\text{SiO}_2$ and $\text{Rh-Mn-Li}/\text{SiO}_2$ catalysts by EPR, since Mn^{2+} is paramagnetic, with in situ reduction treatment⁹⁹. ^{197}Au Mossbauer absorption spectroscopy (MAS), X-ray photoelectron emission (XPS) and TEM were used by Zwijnenburg et al in characterization of gold catalysts supported on TiO_2 and $\text{TiO}_2/\text{SiO}_2$ ¹⁰⁰.

2.3.8 IR and FTIR

Vibrational spectroscopy techniques like IR and FTIR are relevant in the study of the behaviour of precursor compounds during catalyst preparation. For example in order to confirm the conversion of $-\text{CN}$ to $-\text{COOH}$ on thin films pore surface, FTIR was performed on the thin film and the spectrum showed complete disappearance of $-\text{CN}$ stretching vibration along with appearance of $-\text{COOH}$ stretching vibration³⁵ and in another studies, FTIR was used to characterize SBA-15-based chiral rhodium catalysts and the results showed that the catalysts exhibited the general characteristics bands of pure SBA-15¹⁰¹.

2.4 Applications of Coated Capillaries in Reactions

Studying reactions in capillaries required the use of some analytical tools such as ICP, HPLC, GC-MS, NMR, etcetera. These techniques are used to analyse the reaction product and in the long run conclude on the performance of the coated capillary. Some of the reactions studied include:

2.4.1 Enzymatic Reactions

Nakaruma et al. studied enzymatic reactions in a SiO₂ coated capillary microreactor by immobilizing the enzyme on the inner wall of the reactor. The hydrolysis product of the enzyme reaction, unbelliferone, was obtained at high yield in 10 min³⁶. Photocatalytic reaction of methylene blue solution was also carried out by same group in microcapillaries coated with TiO₂ and SiO₂/TiO₂ in which case, the latter showed complete reduction of methylene blue in 40-50 s. In both cases, reactions were monitored using UV – visible spectroscopy.

Figure 2.2 Enzyme immobilization on the inner surface of capillary.

2.4.2 Suzuki-Miyaura

Suzuki-Miyaura reaction of iodobenzene and *p*-tolylboronic acid was studied in a continuous flow capillary coated with palladium complex anchored on macroporous monolith supports⁵⁷. GC-MS analysis of the reaction products (Scheme 4) showed 68% yield of 4-methylbiphenyl and the yield remained constant for 4 days of continuous capillary flow, which demonstrates the application of the method for sustainable continuous flow processes. A Pd leaching of 15-20% after 4 days of operation was calculated from ICP-MS results.

Scheme 4

Gomann et al. used different monolith support in a capillary microreactor to study the Suzuki-Miyaura reaction of aryl halides and *p*-tolylboronic acid⁵⁶ whose products were analyzed using GC-MS and GC-FID. The results showed low activity for the less reactive halides, however the selectivity was very high with small amount of by-product detected for bromobenzene coupling. The researchers also studied Sonogashira coupling reactions of iodobenzene with phenylacetylene (Scheme 5) and high catalytic activity with nearly complete conversion was recorded. After 8 days of continuous operation, leaching of Pd in the capillary was determined to be only 4% loading using ICP-MS.

Scheme 5

Suzuki-Miyaura coupling of aryl boronic acids with bromides were also studied in Pd-coated capillaries and the products analyzed by ^1H NMR¹³. Good to excellent conversions for both electron-rich and electron-poor aryl halides with electron-poor boronic acids were recorded. It was further observed that with the capillaries inside microwave, yield was increased, while in batch reactor, no yield was recorded. ICP-AES analysis showed no leaching of Pd catalyst for up to 2 ppm detection limit. Heck coupling of aryl iodides with acrolein derivatives was also tested and very good conversions were obtained.

2.4.3 Steam Reforming of Methanol

Steam reforming of methanol was studied in a non-porous multi-channeled microreactors coated with $\text{CuO}/\text{ZnO}/\text{Al}_2\text{O}_3$ catalyst and the product analyzed by GC⁷⁸. Both the methanol conversion and CO_2 selectivity were calculated from the analysis of gaseous CO_2 , CO and CH_3OH along with a carbon balance, and 50% methanol conversion was recorded and more than 97% CO_2 selectivity.

Figure 2.3 Fused-silica capillaries combined to form multichanneled capillary

Steam reforming of methanol in alumina, zirconia and 1:1 alumina-zirconia catalysts coated micro-channel reactor was also studied by Kundu et al.⁵¹ and an overwhelming result was obtained with alumina-zirconia mixed catalyst with 99.3% methanol conversion at 290 °C and 0.01 ml.min⁻¹ feed rate.

In another study, steam reforming of methanol was carried out in Cu-Zn-Al₂O₃ catalyst coated microreactor of four different types: based on slurry type; alumina sol-based and DI water based and based on coating method; flow coating and fill-and-dry coating⁴⁸. Analysis of the micro-Gas Chromatograms showed maximum gas production of 118 cm³, of which 85 cm³ was H₂ at 300 °C and methanol feed rate of 9 ml.h⁻¹.

2.4.4 Hydrogenation

Continuous capillary microreactor with mesoporous titania thin films of Pd or Pd₂₅Zn₇₅ nanoparticles was reported to be used in selective hydrogenation of 2-methyl-3-butyne-2-ol^{55a}. GC-MS results showed the major reaction products to be 2-methyl-3-buten-2-ol and 2-methyl-3-butan-2-ol. However, at low hydrogen partial pressure, significant amount of 2,7-dimethyl-3,5-octadiyne-2,7-diol (C₁₀-dimer) was produced. Selective hydrogenation

of phenylacetylene in similar capillary microreactor was also studied under different flow and temperature control^{7a}. The results showed that conversion of phenylacetylene to styrene increased with temperature while selectivity decreased and on the contrary, as liquid flow rate increased, the conversion significantly decreased while selectivity to styrene formation increased. It was observed that the capillary microreactor maintained both activity and selectivity after one month of continuous application.

In the investigation into the kinetics of liquid phase hydrogenation of citral on Au/TiO₂ and Pt-Sn/TiO₂ thin films capillary, it was observed that Pt-Sn/TiO₂ thin film at 343K, liquid residence time of 30 min and a hydrogen partial pressure of 1 gave the highest yield of 79% unsaturated alcohol^{55b}. The reaction orders were found to be 1 for hydrogen over Pt-Sn/TiO₂ and nearly zero for citral over Au/TiO₂ and Pt-Sn/TiO₂ catalysts respectively.

Figure 2.4 Hydrogenation of citral on Au/TiO₂ and Pt-Sn/TiO₂ thin films.

2.4.5 Hydrogen Peroxide and Hydrogen Gas Production

Hydrogen peroxide formation via a capillary microreactor immobilized with palladium was reported by Ng et al⁸². Hydrogen and oxygen flow were controlled separately at flow rates of 2 and 4 ml/min respectively, and were mixed at T-coupling. Then liquid phase was added to the gas stream and the effluent was analyzed using colorimetry while the Pd leaching was measured with ICP-AES. The highest yield of H₂O₂ was obtained with MeOH/HCl/KBr/ as liquid phase solution among the different liquid phase solutions used.

Hydrogen production from ethylene glycol reforming using Rh catalysts supported on CeO₂ and La₂O₃ promoted α -Al₂O₃ was reported⁴⁶. The activity tests were carried out in a lab scale set up and in all the experiments, a steam to carbon mixture (S/C) of 4.0 was used. Complete conversion and selectivity close to the equilibrium were recorded for all tested catalysts, with very low concentration of CH₄ and CH₃CHO by-products. Long-time stability test on the capillaries showed C₂H₄ and C₂H₆ by-products detected in minor amounts.

CHAPTER 3

EXPERIMENTAL

3.1 Chemicals and Materials

Ceric ammonium nitrate, ACS reagent grade was purchased from Riedel-de Haen AG, USA. Phenylacetylene, 65% nitric acid and palladium (ii) nitrate hydrate were purchased from Sigma – Aldrich, USA, while acetylacetone, hexane, ethanol, dimethoxyethane, isopropanol, sodium hydride and sodium borohydride were purchased from Fluka Chemie AG, Buchs, Switzerland. Fused silica capillary, 250 μm diameter was purchased from Polymicro technologies, USA.

3.2 Synthesis of Cerium Isopropoxide

Cerium isopropoxide was synthesized following the procedure described by Vaartstra et al. 1990¹⁰². The experiments were performed using the Schlenk line techniques under continuous nitrogen flow in order to prevent partial hydrolysis by atmospheric moisture. Ceric ammonium nitrate $[(\text{NH}_4)_2\text{Ce}(\text{NO}_3)_6]$ was dried in an oven at 110 $^\circ\text{C}$ for 1 h before being used. Sodium hydride (NaH), anhydrous isopropanol (*i*-PrOH) and dimethoxyethane (DME) were used without further treatment. 22 ml of *i*-PrOH and 14 ml of DME were added to 2.4 g of NaH at 50 $^\circ\text{C}$ and stirred gently. After all the NaH had reacted, 10 ml of DME was added at room temperature, then followed by 9.138 g of $(\text{NH}_4)_2\text{Ce}(\text{NO}_3)_6$ dissolved in a mixture of 14 ml DME and 12 ml *i*-PrOH. The mixture was stirred overnight, then sodium nitrate formed was filtered off, leaving yellow solution of cerium isopropoxide in DME and excess *i*-PrOH. The solvents were removed

from the cerium isopropoxide by rotary evaporation at 50 °C and yellowish cerium isopropoxide was characterized by NMR.

3.3 Synthesis of Palladium Nanoparticles (Pd NPs)

Chemical reduction method of synthesizing nanoparticles reported by Rocio et al.¹⁰³ was adopted because it result in smaller size nanoparticles (2.5 nm). 10^{-3} M solution of palladium (ii) nitrate hydrate ($\text{Pd}(\text{NO}_3)_2 \cdot \text{XH}_2\text{O}$) was prepared by dissolving 23.04 mg of the salt in 100 ml of ethanol solution. In order to avoid agglomeration of nanoparticles, the solution was diluted to 4×10^{-4} M by dissolving 2.5 ml of the stock in 25 ml absolute ethanol.

Freshly prepared 10^{-3} M NaBH_4 solution in ethanol was added dropwise to the palladium salt solution while stirring at moderate rate at room temperature for 1 h.

Complete Palladium ions reduction was investigated using UV-Vis spectrophotometer and the formed nanoparticles were allowed to settle down, then washed in ethanol in order to remove excess NaBH_4 .

3.4 Surface Pretreatment of Capillary

This was done by continuously flowing 1M NaOH into the capillary for 30 min, followed by flushing with demineralized water, after which the capillary was dried and calcined in an oven at 250 °C for 10 h. Surface pretreatment result in the activation of surface silanol of the silica capillary as shown below.

Figure 3.1 Surface pretreatment of fused silica capillary

3.5 Preparation of Sol Solution

Cerium isopropoxide ($\text{Ce}(\text{OPr}^i)_4$) was chosen among other ceria precursors due to its ease of hydrolysis and condensation, thus can be employed to form thin films. The as-synthesized cerium isopropoxide was dissolved in 33.4 ml isopropanol in order to have 0.5 M solution of the precursor. 98.1 μl of acetylacetone (acac-H) was added to 4 ml of the precursor solution in order to prevent precipitation of cerium oxide through chelation of the acetylacetonato groups to cerium¹⁰⁴. The mixture turned yellowish red after 15 min of swirling.

126 mg of Pluronic F127 was dissolved in 1.17 ml of ethanol at 50 °C and was added to 0.36 ml water and 0.161 ml trioxonitrate (V) acid (65 wt.%). To this solution, the acetylacetone-modified precursor solution was added gradually while stirring at 800 rpm at room temperature. The stirring was continued for 24 h at room temperature after which the solution in the form of sol-gel was flowed through a 250 μm diameter capillary for coating. The combining ratio was in the form: 1 $\text{Ce}(\text{OPr}^i)_4$: 0.5 acac-H: 25 *i*-PrOH: 10 EtOH: 10 H_2O : 1 HNO_3 : 0.005 Pluronic F127.

In order to incorporate Pd nanoparticles in the sol-gel, 7.454 mg of as-synthesized nanoparticles were dispersed in the 1.17 ml absolute ethanol and added to the mixture, giving 1 wt.% loading.

The coated capillary was allowed to dry at room temperature under continuous flow of helium gas for 24 h before it was calcined under temperature programming of 25 – 330 °C at ramping of 1 °C/min, hold at 330 °C for 5 h. It was then flushed with absolute

ethanol for 15 min and reconditioned at 40 – 330 °C at ramping of 5 °C/min, hold at 330 °C for 1 h.

Synthesis of $\text{Ce}(\text{OPr}^i)_4$

The hydrolysis and condensation of $\text{Ce}(\text{OPr}^i)_4$ in the capillary can be shown as:

3.6 Characterization of Thin Film

Powder X-ray diffraction pattern (XRD) of the dried thin film was recorded on Rigaku miniflex II X-ray diffractometer in step scan mode between 20 and $90^\circ 2\theta$ (scan rate $0.02^\circ 2\theta s^{-1}$) using $CuK\alpha$ radiation ($\lambda = 1.5414\text{\AA}$). Morphology of thin film on flat glass substrate and inside capillary were obtained using LYRA 3 dual beam field emission scanning electron microscopy (FESEM) at 15.0 kV by making a gold coating in a nitrogen plasma coating unit. Palladium mean particle size was determined from the transmission electron microscope (TEM) image recorded on a Joel-JEM-2100 operated at 200 kV . The scratched thin film were grounded, dispersed in methanol and sonicated for 10 min . One drop of the suspension was dropped on a Cu grid coated with thin layer of carbon. The mean particle diameter was calculated using the relation: $d_m(nm) = 1/100 \sum_{i=1}^{100} n_i d_i$, for n_i number of particles with diameter d_i obtained from the TEM image. Palladium nanoparticle dispersion, %D was determined using the formula: $\%D = 10^7/d_m(nm)$ ¹⁰⁵. FT-IR was carried out on the sol gel using Nicolet 6700 FT-IR spectrometer containing the smart orbit accessory and on the dried thin film, KBr pellet containing 1% of the film was prepared and used for the analysis. Raman spectra was recorded at room temperature, using NXR FT-Raman module spectrograph equipped with InGaAs detector. Data from both FT-IR and XRD were analyzed using Microsoft excel.

3.7 Application of Pd/CeO₂ Capillary in controlled synthesis of styrene and ethylbenzene.

Hydrogenation of phenylacetylene in the Pd/CeO₂ coated capillary microreactor was studied in the range of $30 - 60^\circ\text{C}$ by flowing hydrogen gas through the $250\text{ }\mu\text{m}$ diameter

coated capillary at an angle of 90^0 with respect to the liquid flow. Phenylacetylene in hexane was flowed at constant rate of 0.01 ml.min^{-1} . The coated capillary was placed in a temperature controlled oven with both inlet and outlet tubes. The inlet tube was connected to the microreactor while the outlet was connected to 10 ml vial for product collection. Effects of capillary length, temperature, concentration and gas flow rate on the conversion and selectivity were investigated. The reaction product was collected and analyzed using GC-MS. Metal leaching due to flow of reactants through the capillary was investigated using ICP-MS by evaporating the collected reaction product(s) under reduced pressure and treating the empty vial with 1.5 ml aqua regia and 8.5 ml ultrapure water. The experimental flow diagram for preparation of immobilized Pd NPs capillary is shown below.

Scheme 8.

CHAPTER FOUR

RESULTS AND DISCUSSION

4.1 NMR of $\text{Ce}(\text{OPr}^i)_4$

^1H and $^{13}\text{C}\{^1\text{H}\}$ NMR spectra of $\text{Ce}(\text{OPr}^i)_4$ in CDCl_3 were recorded on Oxford NMR 500 at 300 MHz at 25 °C. From Fig. 4.1, it can be seen that the ^1H NMR showed two chemical shifts (δ): doublet at 1.2 ppm which was attributed to the hydrogen attached to carbon atom carrying the two methyl groups and a septet, enlarged in Fig. 4.2, for the two equivalent methyl protons. The $^{13}\text{C}\{^1\text{H}\}$ NMR showed also two chemical shifts (δ) as shown in Fig. 4.3: one at 25 ppm corresponding to the two equivalent methyl carbon and the other at 65 ppm which was assigned to the carbon carrying the Ce – O bond. Both ^1H and ^{13}C NMR showed only one environment for all the *i*-PrO – groups in the molecule¹⁰².

4.2 UV-Vis spectra of Pd NPs

UV-Vis spectrum was reported to be an effective method to investigate whether metal ions are completely reduced or not¹⁰⁶. The UV-Vis spectrum of palladium (ii) nitrate hydrate solution was measured before reduction and absorption peaks characteristics of the solution were observed at 289 nm and 396 nm as was reported in literature¹⁰⁷. However after addition of NaBH₄, the measured UV-Vis spectra showed no absorption peak, an indication of complete reduction of palladium ions. Fig. 4.4 shows the two UV-Vis spectra for Pd²⁺ and the reduced Pd.

Figure 4.4 UV-Vis spectra of palladium (ii) nitrate hydrate solution and palladium nanoparticles showing peak disappearance.

4.3 Scanning electron microscope of Pd NPs

The SEM of palladium nanoparticles (Fig. 4.5) showed the particles distributed evenly in a form of a chain. According to Yang et al., the proposed mechanism for the formation of this short range ordered linear Pd NP chains is the scaffolding method, with the solvent used as scaffold for the adsorption of Pd(II).

Figure 4.5 FESEM of Pd NPs

4.4 XRD

Powdered XRD pattern (Fig. 4.6) showed Bragg peaks with Miller indices (111), (200), (220), (311) and (222) which were associated with cubic phase fluorite structure of CeO_2 and are in good agreement with the JCPDS file for CeO_2 (JCPDS No. 34-0394). The sharpness of the peaks indicates the high crystallinity of the dried thin film, however upon immobilization of Pd NPs, the intensity got decreased. Similar result was obtained when Pd was supported on carbon-nitrogen composites for hydrogenation of phenol¹⁰⁸. The presence of an unaccounted peak showed the presence of impurity in the thin film which was attributed to the substrate on which the film was coated and dried, then later scratched for the XRD analysis.

Figure 4.6 XRD pattern of CeO₂ thin film dried at 330 °C for 5 h.

4.5 FESEM and TEM

Field emission scanning electron microscope image of Pd/CeO₂ thin film on a glass substrate (Figs. 4.7 and 4.8) showed the thin film is crack free and has a random worm-like network of the mesopore. The nanoparticles are also homogeneous and well dispersed within the pores of ceria thin film. The dispersion of Pd NPs was due to their confinement within the mesopores of ceria. It was also observed that the nanoparticles retained their sizes throughout the process of thermal treatment. Scanning electron microscope of the coated capillary (Fig. 4.9) also showed the homogeneity of the thin film and the thickness of the film was approximately measured to be 200 nm. From Fig. 4.10, TEM image showed Pd NPs well dispersed on the support surface and Pd particles size was determined to be approximately 4.2 nm and its lattice fringes was measured to be 0.22 nm. The corresponding selective area electron diffraction (SAED) pattern shown in Fig. 4.11 confirmed the nanocrystalline nature of Pd/CeO₂ thin film and the d-spacings tabulated in table 4.1 also ascertained the presence of nanocrystalline Pd and CeO₂.

4.6 FTIR

FTIR of the sol gel (Fig. 4.12a) showed broad absorption bands at around 3400 cm^{-1} and 2900 cm^{-1} which were attributed to -OH of the solvents and water and C-H stretching vibrations respectively. Vibration bands at around 1650 cm^{-1} showed the characteristic of acetylacetonato group bounded to cerium atom¹⁰⁹, while bands around 1350 cm^{-1} and 700 cm^{-1} were assigned to Ce-OH and Ce-O-Ce stretching vibrations as reported in literature¹¹⁰. IR spectra of thin film dried at $60\text{ }^{\circ}\text{C}$ and $330\text{ }^{\circ}\text{C}$ (Figs. 4.12b and c) showed the gradual collapse of OH, C-H and acetylacetonato absorption bands, however, absorption bands characteristics of CeO_2 thin film were still observed. Raman spectra of CeO_2 thin film (Fig. 4.14) showed a Raman mode at 461 cm^{-1} and was attributed to the symmetrical stretching mode of Ce-8O vibrational unit¹¹¹. The observed broadening and increased asymmetry of the Raman line, due to the reduction of phonon lifetime in the nanocrystalline regime, explained the microstructure nature of CeO_2 thin film¹¹². Density functional theory (DFT) calculations of CeO_2 using Gaussian 09 revision D. 01 program at DFT-B3LYP/gen with 6-31G* basis set for oxygen atom and SDD basis for cerium, was found to be comparable to the experimental results of CeO_2 thin films as shown in Figs. 4.13 and 4.15.

4.7 Controlled synthesis of styrene and ethylbenzene in Pd/CeO₂ capillary microreactor

Hydrogenation of phenylacetylene in hexane was studied and the products quantified by an external calibration curve. Solution of phenylacetylene as blank, was flowed through the capillary microreactor containing uncoated capillary under the same reaction conditions with the sample under study. Percentage conversion and selectivity were calculated using the formulae:

- %conversion (X)
$$X = 100 \cdot \frac{n}{n_0}$$
- Selectivity (S)
$$S = 100 \cdot \frac{n_i}{n}$$
, where n = amount of reactant converted to product(s), n_0 = initial amount of reactant and n_i = amount of product formed.

Turn over frequency, TOF (s⁻¹) of the Pd/CeO₂ were calculated using the relation:

$$TOF = \frac{\text{reaction rate}}{\text{catalyst active sites}}$$

Catalyst active sites = %D.n, where %D is the Pd NPs dispersion and n is the actual Pd NPs loading in a capillary, determined by flowing aqua regia solution into a freshly coated capillary, then ultrapure water and the collected solution analyzed by ICP-MS^{56, 82}.

4.7.1 Effect of capillary length

By coating 5 – 20 m capillary length with Pd/CeO₂ for capillary microreaction at 0.01 ml.min⁻¹ phenylacetylene flow rate, 0.5 ml.min⁻¹ H₂ flow rate and temperature of 40 °C, gradual increase in phenylacetylene conversion was observed (Fig. 4.16) and became only slightly for 20 m capillary. The increase in conversion was due to increase in the

capillary length which consequently increased phenylacetylene residence time in the microreactor. However slight increase noticed when 20 m capillary was used might be due to decreased uniformity in coating and cracking which usually occur when coating and drying time is long.

Figure 4.16 Effect of capillary length at 0.01 ml.min^{-1} phenylacetylene flow rate and $0.5 \text{ ml.min}^{-1} \text{ H}_2$ flow rate at 40°C .

4.7.2 Effect of temperature

Phenylacetylene hydrogenation over 15 m Pd/CeO₂ capillary was studied in the temperature range 30 – 60 °C, while maintaining a constant H₂ flow rate of 0.05 ml.min⁻¹. From Fig. 4.17, it can be seen that 95% phenylacetylene conversion was recorded at 60 °C, implying that higher conversion was reached at higher temperature. The activation energy from Arrhenius plot (Fig. 4.19) was calculated as 41.36 KJ.mol⁻¹ and was in correlation with those previously reported¹¹³. Increased selectivity towards ethylbenzene from 9.4% at 30 °C to 81.1% at 60 °C was also observed, which is in agreement with previously reported data indicating that product selectivity depends on the reaction temperature^{7a, 55b}. Reverse was the case with styrene, which at 30 °C showed 90.8% selectivity at 21.1% conversion. The turn over frequency (TOF) (Fig. 4.18) also increased from 0.021 s⁻¹ at 30 °C to 0.185 s⁻¹ at 60 °C and this could be accounted on the basis of reaction kinetics where reaction rate increases with temperature increase.

Figure 4.17 Effect of temperature with 15 m Pd/CeO₂ capillary in the range of 30 to 60°C at 0.01 ml.min⁻¹ phenylacetylene flow rate and 0.5 ml.min⁻¹ H₂ flow rate.

Figure 4.18 Conversion and TOF variation with temperature at liquid flow rate of 0.01 ml.min⁻¹ and H₂ flow rate of 0.5 ml.min⁻¹.

Figure 4.19 Arrhenius plot of phenylacetylene hydrogenation, $E_a = 41.36 \text{ kJ.mol}^{-1}$.

4.7.3 Hydrogen gas flow rate

H₂ gas flow rate was varied between 0.25 – 1.5 ml.min⁻¹ over 15 m Pd/CeO₂ capillary at temperature of 60 °C and both conversion and selectivity were found to be effectively changed by the change in flow rate. Maximum conversion and ethylbenzene selectivity was achieved at flow rate of 0.5 ml.min⁻¹ (Fig. 4.20) and as the flow rate increases, both conversion and ethylbenzene selectivity got decreased, but styrene selectivity increased to 86.3% at 1.5 ml.min⁻¹ flow rate. This could be explained on the basis of H₂ adsorption on the Pd active site and the phenylacetylene fluid phase behavior, which below 0.5 ml.min⁻¹ were both not enough for the reaction, but when the flow rate got to 0.5 ml.min⁻¹, the reaction occurred in all domains at comparable level. Above 0.5 ml.min⁻¹, more hydrogen were bubbled into phenylacetylene which reduced the effective reaction volume of the capillary and the mean residence time, hence the observed decrease⁶⁶.

Figure 4.20 Conversion and selectivity response to change in flow rate

4.7.4 Effect of concentration

Phenylacetylene concentration was varied between 10 – 158 ppm over 15 m Pd/CeO₂ capillary at 60 °C, and from Fig. 4.21, it was observed that within the concentration range studied, more than 40% conversion was achieved in all cases, except 10 ppm in which 95% conversion was recorded. However, reaction turn over frequency was observed to increase as the concentration of phenylacetylene increases and this could be accounted for on the basis of reaction kinetics where reaction rate increases with increase in concentration for first and second order kinetics. It was also observed that concentration of phenylacetylene plays a role in the product selectivity. From Fig. 4.22, it can be seen that increasing the concentration favored the formation of styrene as against ethylbenzene, because at 158 ppm, selectivity to ethylbenzene was brought to less than 10%.

Figure 4.21 Effect of phenylacetylene concentration on conversion and TOF

Figure 4.22 Effect of phenylacetylene concentration on conversion and selectivity

4.7.5 Catalyst lifetime

The reusability of the Pd/CeO₂ capillary microreactor for continuous production of the reaction products was evaluated by continuously running the microreactor for 6 days. The operation was stopped however, when more reactant is to be fed into the microreactor. The observed trend showed decrease in phenylacetylene conversion for the first 4 days and was later stabilized until the 6th day of operation. The observed decrease (Fig. 4.23) was attributed to loss of Pd NPs which were not tightly bound to CeO₂ thin film in the Pd/CeO₂ capillary microreactor. ICP-MS analysis of the reaction products collected for the six days of operation showed 38.4% of Pd leaching. This was considered partly due to the friction factor that result from the fast flow rate of phenylacetylene and the lack of capping agent in the immobilized Pd NPs capillary.

Figure 4.23 Phenylacetylene conversion as a function of time

CHAPTER 5

CONCLUSION

Palladium-doped CeO₂ thin film in capillary microreactor was developed for the first time using sol-gel approach. The film precursor was successfully synthesized and characterized following previously reported methodology. The film was characterized using PXRD, FESEM, TEM, FTIR and Raman spectroscopy. The film with thickness of approximately 200 nm was crack free and has a random worm-like network of mesopores. The Pd/CeO₂ capillary was used to study hydrogenation of phenylacetylene in a microreactor at different capillary length, temperature, H₂ flow rate and phenylacetylene concentration. Higher conversion and selectivity towards ethylbenzene was recorded at higher temperature, while selectivity towards styrene was favored at higher phenylacetylene concentration and hydrogen flow rate. Catalyst turn over frequency of 0.733 s⁻¹ was obtained for 158 ppm phenylacetylene hydrogenation at 60 °C and 0.5 ml.min⁻¹ hydrogen flow rate. Catalyst reusability result showed continuous decrease in catalyst activity for first 4 days of operation and then was stabilized for further 2 days. This was as a result of Pd leaching in the Pd/CeO₂ capillary from the ICP-MS analysis of the collected product samples.

RECOMMENDATION

Ellipsometric porosimetry analysis of the thin films should be done in order to determine the pore size and pore volume of the film in the capillary.

Minimization of nanoparticle leaching after flowing of reactants, e.g by adding capping agent such as polyvinylpyrrolidine, should be studied.

The potential of the CeO₂ support in studying other forms of heterogeneous catalysis in microreactor should be harnessed.

Vitae

Name	Abdulkadir Tanimu
Nationality	Nigerian
Date of Birth	22 June 1987
Email	atanimu@abu.edu.ng
Address	No. 94 Imamu Road, Tudun Wada, Zaria-Nigeria

Academic Background

2010 – 2011	Federal College of Education, Zaria, Nigeria Professional diploma in education (credit) Project title: The problems of teaching chemistry in secondary school within Zaria zone, Kaduna State, Nigeria.
2004 – 2009	Ahmadu Bello University, Zaria-Nigeria. B.Sc. Chemistry (second class upper) Project title: Kinetics and Mechanisms of the electron-transfer reaction of malachite green with hydroxyl ion in aqueous medium. Supervisor: Dr. S.O. Idris
1999 – 2004	Government Secondary School, Zaria-Nigeria Secondary School Certificate Examination (SSCE)
1994 – 1999	God's Time School, Tudun Wada, Zaria Primary School Certificate

EXPERIENCE

Graduate Assistant:	Ahmadu Bello University-Zaria, Nigeria From June, 2011 – date
Graduate Assistant:	Kaduna State University, Kaduna State, Nigeria From April, 2011 – June, 2011
Assistant Lecturer:	Federal College of Education, Zaria, Nigeria From October, 2010 – April, 2011

AWARD

King Fahd University of Petroleum and Minerals M.Sc. Graduate Scholarship Award
BALCOM Computer Institute Award for best graduating secondary school student

PUBLICATIONS

Kinetics of redox reaction of malachite green and hydroxyl ion. **Tanimu A.**, Idris S.O., Iyun J.F. (2012). *International journal of science and technology*, 2 (3), 112-115.

Kinetics and Mechanism of the Reaction of Malachite Green and Dithionite Ion. Idris, S. O., **Tanimu, A.**, Iyun, J. F., & Mohammed, Y. (2015). *International Research Journal of Pure & Applied Chemistry*, 5(2), 177-184.

Kinetics and Mechanism of Malachite Green Oxidation by Hypochlorite Ion in Aqueous Acidic Medium. . Idris, S. O., **Tanimu, A.**, Iyun, J. F., & Mohammed, Y. (2015). *American Chemical Science Journal*, 5(2), 185-193.
